"VIDEO CODING METHOD AND DEVICE"

5 **FIELD OF THE INVENTION**

The present invention relates to a three-dimensional (3D) video coding method for the compression of a bitstream corresponding to an original video sequence that has been divided into successive groups of frames (GOFs) the size of which is $N = 2^n$ with $n = 0, 1, 2, \dots$, said coding method comprising the following steps, applied to each successive GOF of the

10

sequence :

a) a spatio-temporal analysis step, leading to a spatio-temporal multiresolution decomposition of the current GOF into 2^n low and high frequency temporal subbands, said step itself comprising :

15

- a motion estimation sub-step ;
- based on said motion estimation, a motion compensated temporal filtering sub-step, performed on each of the 2^{n-1} couples of frames of the current GOF ;
- a spatial analysis sub-step, performed on the subbands resulting from said temporal filtering sub-step ;

20

b) an encoding step, performed on said low and high frequency temporal subbands resulting from the spatio-temporal analysis step and on motion vectors obtained by means of said motion estimation step and delivering an embedded coded bitstream.

The invention also relates to a video coding device for carrying out said coding method.

25

BACKGROUND OF THE INVENTION

Video streaming over heterogeneous networks requires a high scalability capability. That means that parts of a bitstream can be decoded without a complete decoding of the sequence and can be combined to reconstruct the initial video information at lower spatial or temporal resolutions (spatial/temporal scalability) or with a lower quality (PSNR or bitrate scalability). A convenient way to achieve all these three types of scalability (scalable, temporal, PSNR) is a three-dimensional (3D, or 2D + t) subband decomposition of the input video sequence, after a motion compensation of said sequence.

30

35

Current standards like MPEG-4 have implemented limited scalability in a predictive DCT-based framework through additional high-cost layers. More efficient solutions based on a three-dimensional subband decomposition followed by a hierarchical encoding of the spatio-temporal trees – performed by means of an encoding module based on the technique named Fully Scalable Zerotree (FSZ) – have been recently proposed as an extension of still image coding techniques for video : the 3D or (2D+t) subband decomposition provides a natural

spatial resolution and frame rate scalability, while the in-depth scanning of the coefficients in the hierarchical trees and the progressive bitplane encoding technique lead to the desired quality scalability. A higher flexibility is then obtained at a reasonable cost in terms of coding efficiency.

5 The ISO/IEC MPEG normalization committee launched at the 58th
Meeting in Pattaya, Thailand, December 3-7, 2001, a dedicate AdHoc Group (AHG on
Exploration of Interframe Wavelet Technology in Video Coding) in order to, among
other things, explore technical approaches for interframe (e.g. motion-compensated)
10 wavelet coding and analyze in terms of maturity, efficiency and potential for future
optimization. The codec described in the document PCT/EP01/04361 (PHFR000044)
is based on such an approach, illustrated in Fig.1 that shows a temporal subband
decomposition with motion compensation. This 3D wavelet decomposition with
15 motion compensation is applied to a group of frames (GOF), these frames being
referenced F1 to F8 and organized in successive couples of frames. Each GOF is
motion-compensated (MC) and temporally filtered (TF), thanks to a Motion
Compensated Temporal Filtering (MCTF) module. At each temporal decomposition
level, resulting low frequency temporal subbands are further filtered and the process
20 stops when there is only one temporal low frequency subband left (the root temporal
subband called LLL in Fig.1 where three stages of decomposition are shown : L and
H = first stage ; LL and LH = second stage ; LLL and LLH = third stage),
representing a temporal approximation of the input GOF. Also at each decomposition
level, a group of motion vector fields is generated (in Fig.1, MV4 at the first level,
MV3 at the second one, MV2 at the third one). After these two operations performed
25 in the MCTF module, the frames of the temporal subbands thus obtained are further
spatially decomposed and yield a spatio-temporal tree of subband coefficients.

With Haar filters used for the temporal filtering operations, motion
estimation (ME) and motion compensation (MC) are only performed every two
frames of the input sequence, the total number of ME/MC operations required for
the whole temporal tree being roughly the same as in a predictive scheme. Using
30 these very simple filters, the low frequency temporal subband represents a temporal
average of the input couple of frames, whereas the high frequency one contains the
residual error after the MCTF operation.

One of the main parameters that has been identified as being relevant
for the MCTF module of a motion compensated 3D subband video coding scheme is
35 the so-called "ME Activation" (or motion estimation activation), in other words the
decision to perform or not ME on a couple of input frames (for the first temporal
level) or subbands (for the following levels). For high motion activity sequence, it has
been observed that using ME and therefore performing temporal filtering along
motion trajectories do increase the overall coding efficiency. However, this gain in

coding efficiency may be lost in case of decoding at low bit-rate (one must keep in mind that the decoding bit-rate is a priori unknown in the framework of scalable coding), due to a too possible high overhead for motion vectors. So it may be more efficient in certain circumstances to decide not to activate ME so as to keep as much as possible bit-rate for texture coding (and decoding).

SUMMARY OF THE INVENTION

It is therefore an object of the invention to propose an encoding method avoiding the conventional solutions encountered in current MC 3D subband video coding schemes, in which ME Activation within a MCTF module is either arbitrarily chosen or derived from some information obtained a posteriori, i.e. only after having actually performed MCTF.

To this end, the invention relates to a coding method such as defined in the introductory paragraph of the description and which is moreover characterized in that said spatio-temporal analysis step also comprises a decision sub-step for activating or not the motion estimation sub-step, said decision sub-step itself comprising a motion activity pre-analysis operation based on the MPEG-7 Motion Activity descriptors and performed on the input frames or subbands to be motion compensated and temporally filtered.

According to a particularly advantageous implementation, said method is characterized in that said decision sub-step, based on the *Intensity of activity* attribute of the MPEG-7 Motion Activity Descriptors for all the frames or subbands of the current temporal decomposition level, comprises the following operations :

1) for a specific temporal decomposition level :

a) perform ME between each couple of frames (or subbands) that compose this level :

- for each couple :

- compute the standard deviation of motion vector magnitude ;
- compute the Activity value.

b) compute the average Activity Intensity $I(av)$:

- if $I(av)$ is equal to 5 (value corresponding to "very high intensity"), it is decided to deactivate ME for respectively the current temporal decomposition level and the following levels as well ;

- If $I(av)$ is strictly below 5, it is decided to activate ME for the current temporal decomposition level.

2) go to the next temporal decomposition level.

Since the ME deactivation for a specific level results in the ME deactivation for the following levels, this technical solution leads to a significant complexity reduction of the overall MCTF module, while still offering a good compression efficiency and above all a good compromise between motion vector overhead and picture quality.

It is another object of the invention to propose a coding device for carrying out such a coding method.

BRIEF DESCRIPTION OF THE DRAWINGS

The present invention will now be described, by way of example, with reference to the accompanying drawings in which :

Fig.1 illustrates the conventional case of the temporal subband decomposition of an input video sequence with motion compensation ;

Fig.2 illustrates the case in which, according to the invention, ME is activated for only the first temporal decomposition level and deactivated for the following levels.

DETAILED DESCRIPTION OF THE INVENTION

As seen above, the whole efficiency of any MC 3D subband video coding scheme depends on the specific efficiency of its MCTF module in compacting the temporal energy of the input GOF. As the parameter "ME Activation" is now known to be a major one for the success of MCTF, it is proposed, according to the invention, to derive this parameter from a dynamical Motion Activity pre-analysis of the input frames (or subbands) to be motion-compensated temporally filtered, using normative (MPEG-7) motion descriptors (see the document "Overview of the MPEG-7 Standard, version 6.0", ISO/IEC JTC1/SC29/WG11 N4509, Pattaya, Thailand, December 2001, pp.1-93). The following description will define which descriptor is used and how it influences the choice of the above-mentioned encoding parameter.

In the 3D video coding scheme described above, ME/MC is generally arbitrarily performed on each couple of frames (or subbands) of the current temporal decomposition level. It is now proposed to either activate or deactivate ME according to the "*Intensity of activity*" attribute of the MPEG-7 Motion Activity Descriptors, and this for all the frames - or subbands - of the current temporal decomposition level (*Intensity of activity* takes its integer values within the [1, 5] range : for instance 1 means a "very low intensity" and 5 means "very high intensity"). This Activity Intensity attribute is obtained by performing ME as it would be done anyway in a conventional MCTF scheme and using statistical properties of the motion-vector magnitude thus obtained. Quantized standard deviation of motion-vector magnitude is a good metric for the motion Activity Intensity, and Intensity value can be derived from the standard deviation using thresholds. The ME Activation will therefore be obtained as now described :

2) for a specific temporal decomposition level :

a) perform ME between each couple of frames (or subbands) that compose this level :

- for each couple :

- compute the standard deviation of motion vector magnitude ;
- compute the Activity value.

b) compute the average Activity Intensity $I(av)$:

5 - if $I(av)$ is equal to 5 (value corresponding to "very high intensity"), it is decided to deactivate ME for respectively the current temporal decomposition level and the following levels as well ;

 - if $I(av)$ is strictly below 5, it is decided to activate ME for the current temporal decomposition level.

10 3) go to the next temporal decomposition level.

If ME is activated for a specific level, based on such a pre-analysis, motion vectors are already computed and can be directly used for MCTF of that level. On the contrary, if ME is deactivated, the motion vectors pre-computed for the needs of the pre-analysis are then useless and can be discarded. Moreover, the ME deactivation for a specific level results in the ME deactivation for the following levels, which leads to a reduction of complexity of the overall MCTF module, as illustrated for example in Fig.2 corresponding to the case in which ME is only activated for the first temporal decomposition-level and deactivated for the following ones.

CLAIMS :

1. A three-dimensional (3D) video coding method for the compression of a bitstream corresponding to an original video sequence that has been divided into successive groups of frames (GOFs) the size of which is $N = 2^n$ with $n = 0, 1, 2, \dots$, said coding method comprising the following steps, applied to each successive GOF of the sequence :

a) a spatio-temporal analysis step, leading to a spatio-temporal multiresolution decomposition of the current GOF into 2^n low and high frequency temporal subbands, said step itself comprising :

- a motion estimation sub-step ;
- based on said motion estimation, a motion compensated temporal filtering sub-step, performed on each of the 2^{n-1} couples of frames of the current GOF ;
- a spatial analysis sub-step, performed on the subbands resulting from said filtering sub-step ;

b) an encoding step, performed on said low and high frequency temporal subbands resulting from the spatio-temporal analysis step and on motion vectors obtained by means of said motion estimation step and delivering an embedded coded bitstream ;
said coding method being further characterized in that said spatio-temporal analysis step also comprises a decision sub-step for activating or not the motion estimation sub-step, said decision sub-step itself comprising a motion activity pre-analysis operation based on the MPEG-7 Motion Activity descriptors and performed on the input frames or subbands to be motion compensated and temporally filtered.

2. A coding method according to claim 1, said decision sub-step being based on the *Intensity of activity* attribute of the MPEG-7 Motion Activity Descriptors for all the frames or subbands of the current temporal decomposition level and comprising the following operations :

1) for a specific temporal decomposition level :

a) perform ME between each couple of frames (or subbands) that compose this level :

- for each couple :
 - compute the standard deviation of motion vector magnitude ;
 - compute the Activity value.

b) compute the average Activity Intensity $I(av)$:

- if $I(av)$ is equal to 5 (value corresponding to "very high intensity"), it is decided to deactivate ME for respectively the current temporal decomposition level and the following levels as well ;

- if $I(av)$ is strictly below 5, it is decided to activate ME for the current temporal decomposition level.

2) go to the next temporal decomposition level.

3. A video coding device for the compression of a bitstream corresponding to an original video sequence that has been divided into successive groups of frames (GOFs) the size of which is $N = 2^n$ with $n = 0, 1, 2, \dots$, said coding device comprising the following elements :

5 a) spatio-temporal analysis means, applied to each successive GOF of the sequence and leading to a spatio-temporal multiresolution decomposition of the current GOF into 2^n low and high frequency temporal subbands, said analysis means themselves comprising :

- a motion estimation circuit ;

- based on the result of said motion estimation, a motion compensated temporal filtering circuit, applied to each of the 2^{n-1} couples of frames of the current GOF ;

10 - a spatial analysis circuit, applied to the subbands delivered by said temporal filtering circuit ;

b) encoding means, applied to the low and high frequency temporal subbands delivered by said spatio-temporal analysis means and to motion vectors delivered by said motion estimation circuit, said encoding means delivering an embedded coded bitstream ;

15 said coding device being further characterized in that said spatio-temporal analysis means also comprise a decision circuit for activating or not the motion estimation circuit, said decision circuit itself comprising a motion activity pre-analysis stage, using the MPEG-7 Motion Activity descriptors and applied to the input frames or subbands to be motion compensated and temporally filtered.

Abstract

The invention relates to a three-dimensional (3D) video coding method for the compression of a coded bitstream corresponding to an original video sequence that has been divided into successive groups of frames (GOFs). This method, applied to each GOF of the sequence, comprises (a) a spatio-temporal analysis step, leading to a spatio-temporal multiresolution decomposition of the current GOF into low and high frequency temporal subbands and itself comprising a motion estimation sub-step, a motion compensated temporal filtering sub-step, and a spatial analysis sub-step ; (b) an encoding step, performed on said low and high frequency temporal subbands and on motion vectors obtained by means of said motion estimation step. According to the invention, said spatio-temporal analysis step also comprises a decision sub-step for activating or not the motion estimation sub-step, said decision sub-step itself comprising a motion activity pre-analysis operation based on the MPEG-7 Motion Activity descriptors and performed on the input frames or subbands to be motion compensated and temporally filtered.
